

Transitioning to Configurable Joins

Configurable Joins are a powerful tool to query your database. As you transition from Local or Slate Template Library (STL) queries to queries that use Configurable Joins, you'll encounter a few differences in features and terminology. This article will provide an overview of familiar aspects of Local and STL queries, along with their equivalents in Configurable Joins.

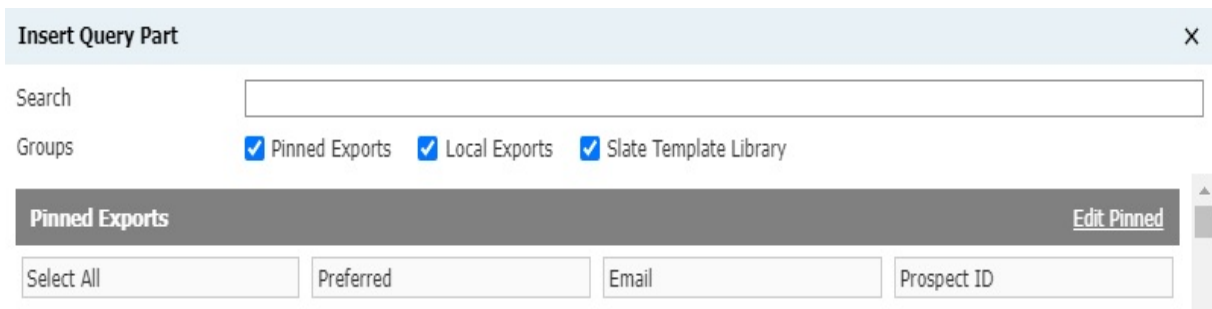

Bases

Due to the flexibility and power of Configurable Joins, there are many more bases than in the STL. We [provide a list of every base and what it does](#). However, it's worth highlighting some commonly-used STL bases and their equivalent in Configurable Joins:

Local / STL	Configurable Joins
Prospects base	Person base; add a filter to exclude opt-outs
Prospects (including opt-outs) base	Person base
Prospects and Applicants base	Person base; join to Application by Rank (Rank = 1)

Saved Query Parts

In Local/STL queries, exports and filters could be saved to a "pinned" section at the top of the Insert Query Part popup window, making it easy to find commonly used query parts.

In Configurable Joins, you can use [query libraries](#) to achieve the same result. Library exports, filters, and joins are shown at the top of the Insert Query Part popup window.

Export Types

There are two types of exports that are slightly different in Configurable Joins:

Local / STL	Configurable Joins
<p>Formula export</p> <div style="border: 1px solid #ccc; padding: 5px; width: fit-content;"> Σ Formula </div>	<p>Subquery export - Set Output to Formula</p> <div style="border: 1px solid #ccc; padding: 5px; width: fit-content;"> Export </div>
<p>Existence export</p> <div style="border: 1px solid #ccc; padding: 5px; width: fit-content;"> 🌐 Existence </div>	<p>Subquery export - Set Output to Existence</p> <div style="border: 1px solid #ccc; padding: 5px; width: fit-content;"> Export </div>

Existence Filters

A common type of filter is one that checks for the existence of a field or related item.

Local / STL	Configurable Joins
<p>Field Value Exists</p> <p>Edit Part X</p> <p>Status: <input type="text" value="Active"/> ▾</p> <p>Name: Field Value Exists</p> <p>Source: Filter</p> <p>Memo: Returns results where prospect field value exists/ does not exist</p> <p>Matching Rows: 100,000</p> <p>Field Value Exists: <input type="text" value="EXISTS"/> ▾</p> <p><input type="text" value="Other - Entry Term"/> ▾</p>	<p>Subquery filter - Add the relevant export</p> <p>Edit Part X</p> <p>Status: <input type="text" value="Active"/> ▾</p> <p>Name: <input type="text" value="Entry Term Exists"/></p> <p>Source: Subquery Filter</p> <p>Type: <input type="text" value="Dependent subquery"/> ▾</p> <p>Aggregate: <input type="text" value="Exists"/> ▾</p> <p>Exports: <input type="text" value="Export"/> <input type="text" value="Person Entry Term"/></p> <p>Filters: <input type="text" value="Filter"/> <input type="text" value="NOT"/> (<input type="text" value="OR"/>) <input type="text" value="Join"/></p>
<p>Has Related Item (for example, Has School Level of Study)</p> <p>Edit Part X</p> <p>Status: <input type="text" value="Active"/> ▾</p> <p>Name: Has School Level of Study</p> <p>Source: Filter</p> <p>Memo: Returns prospects that have or do not have a school of the selected Level of Study.</p> <p>Matching Rows: 0</p> <p>Has School Level of Study: <input type="text" value="IN"/> ▾</p> <div style="border: 1px solid black; padding: 5px; margin-top: 5px;"> <p>Graduate</p> <p style="background-color: #007bff; color: white;">High School</p> <p>Undergraduate</p> <p>No Level Listed</p> </div>	<p>Subquery filter - Join to the relevant table and add a filter</p> <p>Edit Part X</p> <p>Status: <input type="text" value="Active"/> ▾</p> <p>Name: <input type="text" value="Has School - High School"/></p> <p>Source: Subquery Filter</p> <p>Type: <input type="text" value="Dependent subquery"/> ▾</p> <p>Aggregate: <input type="text" value="Exists"/> ▾</p> <p>Exports: <input type="text" value="Export"/> <input type="text" value="Person Entry Term"/></p> <p>Filters: <input type="text" value="Filter"/> <input type="text" value="NOT"/> (<input type="text" value="OR"/>) <input type="text" value="Join"/> <input type="text" value="Settings"/></p> <p>Join: Schools</p> <p><input type="text" value="Schools / Type/Level of Study IN High School"/></p>

Related Information

Base joins are the most straightforward way to link related information in the database. The STL provides information from many related tables in Slate. In Configurable Joins, this information can be exported by adding a **base join**. This section lists some common data points from the STL and what base join to choose to access this information in Configurable Joins.

Many of these joins use **rank**. Despite its name, rank has nothing to do with rating or grading records - it's how Slate determines which items are the *most relevant*. For example, a student's Rank 1 Application is the application that Slate thinks you're most likely to query on. You can read about [how ranks are determined](#) if you'd like to know the details.

Person Base Joins

Here are some common base joins for queries in the Person base.

Local / STL	Base Join
Active Address	Address by Rank Overall (Rank = 1)
Interest #1	Interest by Rank (Rank = 1)
Job #1	Job by Rank (Rank = 1)
Mailing Address	Address by Type, Rank (Type = Mailing Address, Rank = 1)
Origin Source	Origin Source by Group and First/Last selection
Permanent Address	Address by Type, Rank (Type = Permanent Address, Rank = 1)
School #1	School by Rank Overall (Rank = 1)
School #1 Organization Details	Join from School by Rank Overall (Rank = 1) to Organizations
School #1 Address	Join from School by Rank Overall (Rank = 1) to Organizations; then join from Organizations to Address by Rank Overall (Rank = 1)

What about applications?

Wondering how to get application information from the Person query base? The Person base has one row per person record, but a person can have multiple applications. To add application information, you must specify which application should be joined.

- **Application by Rank** joins an application using its rank, regardless of whether it has been submitted. Adding this base join and setting Rank = 1 is equivalent to the "Prospects and Applicants" query base from the STL.
- **Application by Rank Submitted** joins a submitted application using its rank.

Application Base Joins

Here are some common base joins for queries in the Application base.

Local / STL	Base Join
All Person information	Person <i>Once you've added this base join, you can add additional base joins for the information in the Person table above.</i>
Application Details: Bin	Current Bin
Application Details: Round	Lookup Round
Application Details: Period	Join from Lookup Round to Lookup Period
Decision #1	Decision by Rank (Rank = 1)
Decision (First)	Decision by Rank Reverse (Rank = 1)
Decision Most Recent Confirmed	Decision by Rank Confirmed (Rank = 1)
Decision Most Recent Released	Decision by Rank Released (Rank = 1)
Decision Most Recent Released (Received)	Use a subquery (<i>see next section</i>)

Complex Logic

Many of the exports and filters in the STL use logic that's more complex than individual base joins. They may make complicated joins, perform calculations across multiple rows, or transform the data in other ways. In Configurable Joins, complex logic often requires [subquery exports](#) and [subquery filters](#) described in the linked articles.
